About libreant

Libreant is a book manager for both digital and paper documents. It can store any kind of digital data actually, not only books. It's db structure makes Libreant highly customizable, documents can be archived by their types with different metadata set, moreover you can create your own preset and choose default descriptors for that kind of volume. The search function looks through the db, and rank matches powered by ElasticSearch. The language of metadata (as title, or description) is a compulsory field, since the db will use it to optimize the search.

Elements into Libreant are defined as volumes, for each volume you can attach many files, usually these files are pdf or book scans. Libreant is built and intended as a federation of nodes, every node is an archive. From a node you can search into friend-nodes, with OpenSearch protocol. Possible extensions into Web are suspended.

Libreant aims to share, find and save books. It can be used by a librarian who needs an archive system or to collect digital items in a file sharing project.

Libreant is created by InsomniaLab, a hacklab in Rome. For any doubts, suggestion or similar write to: insomniac@hacari.org

Libreant is Ubercool

Libreant architecture

Libreant is meant to be a distributed system. Actually, you can even think of nodes as standalone-systems. A node is not aware of other nodes. It is a single point of distribution with no knowledge of other points.

The system that binds the nodes together is the aggregator; an aggregator acts only as a client with respect to the nodes. Therefore multiple aggregators can coexist. This also implies that the node administration does not involve the management of the aggregation mechanism and of the aggregators themselves. Similarly, it is possible to run an aggregator without running a libreant node. As a consequence, a node cannot choose whether to be aggregated or not.

The aggregation mechanism is based on [Opensearch](#), and relies on two mandatory fields:

- the Opensearch [description](#)
- the Opensearch [response](#)

meaning that this entries are mandatory on a node in order to be aggregated. The result component heavily relies on the [relevance](#) extension of the response spec.

We blindly trust this relevance field, so a malicious node could bias the overall result, simply increasing the relevance fields of its entries. In this way, the management of the aggregators implies also the task of checking the fairness of the aggregated nodes.

2.1 How to set up an aggregator

1. Install Libreant. Follow the instructions on [Installation](#).
2. Launch Libreant setting the `AGHERANT_DESCRIPTIONS` configuration parameters. Its value should be a list of URLs. Each URL represents the Opensearch description. For Libreant it's located in `/description.xml`, so a typical URL looks like:

```
http://your.doma.in/description.xml
```

and a typical invocation looks like:

```
libreant --agherant-descriptions "http://your.doma.in/description.xml http://other.node/description.xml"
```

If you want to aggregate the same libreant instance that you are running, there's a shortcut: just use `SELF`. Here's an example:

```
libreant --agherant-descriptions "SELF http://other.node/description.xml"
```

Note: Through *agherant* command line program, it's possible to run an aggregator without launching the whole libreant software

Librarian

This chapter is dedicated to librarians, people who manage the libreant node, decide how to structure the database, organize informations and supervise the catalogue.

3.1 Presets system

One of the things that make libreant powerful is that there are almost no assumptions and restrictions about informations you can catalog with it. You can use libreant to store digital book, organize physical book metadata, CDs, comics, organization reports, posters and so on.

Stored object informations are organized in a collection of key-values pairs:

```
title:   Heart of Darkness
author:  Joseph Conrad
year:    1899
country: United Kingdom
```

Normally, when users insert new objects in the database they can choose the number and the type of key-values pairs to save, without any restrictions. Language field is the only one information that is always required.

All this freedom could be difficult to administrate, so libreant provide the preset system as a useful tool to help librarians.

3.1.1 Preset

A preset is a set of rules and properties that denote a class of object. For example, if you want to store physical book metadata in your libreant node and for every book you want to remember the date in which you bought that book, in this case you can create a preset for class `bought-book` that has always a property with id `date`.

3.1.2 Quick steps creation

To create a new preset you need to create a new json file, populate it and configure libreant to use it.

Every preset is described by one json formatted text file. So in order to create a new preset you need to create a new text file with `.json` extension. This is the simplest preset you can do:

```
{
  "id": "bought-book",
  "properties": []
}
```

Once you have created all your presets you can use the `PRESET_PATHS` configuration variable to make libreant use them. `PRESET_PATHS` accepts a list of paths (strings), you can pass paths to file or folders containing presets.

Start libreant and go to the add page, you should have a list menu from which you can choose one of your presets. If some of your presets are not listed, you can take a look at log messages to investigate the problem.

3.1.3 Preset structure

The preset file has some general fields that describe the matadata of the preset (id, description, etc...) and a list of properties describing informations that objects belonging to this preset must/should have.

Preset example:

```
{
  "id": "bought-book",
  "allow_upload": false,
  "description": "bought physical book",
  "properties": [{ "id": "title",
                  "description": "title of the book",
                  "required": true
                },
                { "id": "author",
                  "description": "author of the book",
                  "required": true
                },
                { "id": "date",
                  "description": "date in which book was bought",
                  "required": true
                },
                { "id": "genre",
                  "description": "genre of the book",
                  "required": true,
                  "type": "enum",
                  "values": ["novel", "scientific", "essay", "poetry"]
                }
              ]
}
```

General fields:

Key	Type	Required	Default	Description
id	string	True		id of the preset
description	string	False	""	a brief description of the preset
allow_upload	boolean	False	True	permits upload of files during submission
properties	list	True		list of properties

Property fields:

Key	Type	Required	Default	Description
id	string	True		id of the property
description	string	False	""	a brief description of the property
required	boolean	False	False	permits to leave this property empty during submission
type	string	False	"string"	the type of this property
values	list	<i>Enum type</i>		used if type is "enum"

String type

String type properties will appear in the add page as a plain text field.

Enum type

Enum type properties will appear in the add page as a list of values. Possible values must be placed in *values* field as list of strings. *values* field are required if the type of the same property is “enum”.

4.1 Installation

4.1.1 System dependencies

Debian wheezy / Debian jessie / Ubuntu

Download and install the Public Signing Key for elasticsearch repo:

```
wget -qO - http://packages.elasticsearch.org/GPG-KEY-elasticsearch | sudo apt-key add -
```

Add elasticsearch repos in /etc/apt/sources.list.d/elasticsearch.list:

```
echo "deb http://packages.elasticsearch.org/elasticsearch/1.4/debian stable main" | sudo tee /etc/apt/sources.list.d/elasticsearch.list
```

Install requirements:

```
sudo apt-get update && sudo apt-get install python2.7 gcc python2.7-dev python-virtualenv openjdk-7-jre
```

Note: if you have problem installing elasticsearch try to follow the [official installation guide](#)

Arch

Install all necessary packages:

```
sudo pacman -Sy python2 python2-virtualenv elasticsearch
```

4.1.2 Python dependencies

Create a virtual env:

```
virtualenv -p /usr/bin/python2 ve
```

Install libreant and all python dependencies:

```
./ve/bin/pip install libreant
```

4.2 Execution

4.2.1 Start elasticsearch

Debian wheezy / Ubuntu

Start elasticsearch service:

```
sudo service elasticsearch start
```

Note: If you want to automatically start elasticsearch during bootup:

```
sudo update-rc.d elasticsearch defaults 95 10
```

Arch / Debian jessie

Start elasticsearch service:

```
sudo systemctl start elasticsearch
```

Note: If you want to automatically start elasticsearch during bootup:

```
sudo systemctl enable elasticsearch
```

4.2.2 Start libreant

To execute libreant:

```
./ve/bin/libreant
```

How to write documentation

We care a lot about documentation. So this chapter is both about technical reference and guidelines.

5.1 Markup language

Documentation is written using `restructuredText`; it's a very rich markup language, so learning it all may be difficult. You can start reading a [quick guide](#); you can then pass to a slightly [longest guide](#).

As with all the code, you can learn much just reading pre-existing one. So go to next section and you'll know where it is placed.

5.2 Documentation directory

Documentation is placed in `doc/source/` in libreant repository. Yes, it's just a bunch of `.rst` files. The main one is `index.rst`, and hist main part is the `toctree` directive; the list below it specifies the order in which to include all the other pages.

Note: If you are trying to add a new page to the documentation, remember to add its filename to the `toctree` in `index.rst`

To build html documentation from it, you should first of all `pip install Sphinx` inside your virtualenv. Then you can run `python setup.py build_sphinx`. This command will create documentation inside `build/sphinx/html/`. So run `firefox build/sphinx/html/index.html` and you can read it.

See also:

Installation

5.3 Documenting code

If you are a developer, you know that well-documented code is very important: it makes newcomers more comfortable hacking your project, it helps clarifying what's the goal of the code you are writing and how other parts of the project should use it. Keep in mind that libreant must be easily hackable, and the code should be kept reusable at all levels as much as possible.

Since 99% of libreant code is Python, we'll focus on it, and especially on python docstrings.

If you are writing a new module, or anyway creating a new file, the “module docstring” (that is, the docstring just at the start of the file) should explain what this module is useful for, which kind of objects will it contain, and clarify any possible caveat.

The same principle applies to classes and, to a lesser degree, to methods. If a class docstring is complete enough, it can be the case that function docstring is redundant. Even in that case, you should at least be very careful in giving meaningful names to function parameters: they help a lot, and come for free!

How to develop

This chapter is dedicated to developers, and will guide you through code organization, design choices, etc. This is not a tutorial to python, nor to git. It will provide pointers and explanation, but will not teach you how to program.

6.1 Ingredients

libreant is coded in python2.7. Its main components are an [elasticsearch](#) db, a [Fsdb](#) and a web interface based on [Flask](#).

6.1.1 Details about libraries

Elasticsearch is a big beast. It has a lot of features and it can be scaring. We can suggest this [elasticsearch guide](#). The python library for elasticsearch, [elasticsearch-py](#), is quite simple to use, and has a nice documentation.

[Fsdb](#) is a quite simple “file database”: the main idea behind it is that it is a content-addressable storage. The address is simply the sha1sum of the content.

[Flask](#) is a “web microframework for python”. It’s not a big and complete solution like django, so you’ll probably get familiar with it quite soon.

6.2 Installation

6.2.1 Using virtualenv

We will assume that you are familiar with virtualenvs. If you are not, please get familiar!

Inside a clean virtualenv, run

```
python setup.py develop
```

You are now ready to develop. And you’ll find two tools inside your `$PATH`: `webant` and `libreant-manage`. The first is a webserver that will run the web interface of libreant, while the second is a command-line tool to do basic operations with libreant: exporting/importing items, searching, etc.

6.2.2 Using Vagrant

Download, setup and run the virtual machine:

```
vagrant up
```

You will then find in `/liberant` the installation of liberant, you can login to the vagrant box with:

```
vagrant ssh
```

6.3 Code design

This section is devoted to get a better understanding on why the code is like it is, the principles that guides us, and things like that.

6.3.1 Design choices

few assumptions about data We try to be very generic about the items that libreant will store. We do not adhere to any standard about book catalogation, nor metadata organization, nor nothing like that. We leave the libraries free to set metadata how they prefer. There is only one mandatory field in items, which is `language`. The reason it is this way, is that it's important to know the language of the metadata in order for full-text search to work properly. There are also two somewhat-special fields: `title` and `actors`; they are not required, but are sometimes used in the code (being too much agnostic is soo difficult!)

no big framework we try to avoid huge frameworks like django or similar stuff. This is both a precise need, and a matter of taste. First of all, libreant uses many different storage resources (elasticsearch, fsdb, and this list will probably grow), so most frameworks will not fit our case. But it's also because we want to avoid that the code is "locked" in a framework and therefore difficult to fork.

6.3.2 File organization

`setup.py` is the file that defines how libreant is installed, how are packages built, etc. The most common reason you could care about it, is if you need to add some dependency to libreant.

libreantdb

`libreantdb/` is a package containing an abstraction over elasticsearch. Again: this is elasticsearch-only, and completely unaware of any other storage, or the logic of libreant itself.

webant

`webant/` is a package; you could think that it only contains web-specific logic, but this is not the case. Instead, all that is not in `libreantdb` is in `webant`, which is surely a bit counterintuitive.

The web application (defined in `webant.py`) "contains" a [Blueprint](#) called `agherant`. Agherant is the part of libreant that cares about "aggregating" multiple nodes in one single search engine. We believe that agherant is an important component, and if we really want to make libreant a distributed network, it should be very reusable. That's why agherant is a blueprint: it should be reusable easily.

`manage.py` is what will be installed as `libreant-manage`: a simple command-line manager for lot of libreant operations. `libreant-manage` is meant to be a tool for developers (reproduce scenarios easily) and sysadmins

(batch operations, debug), surely not for librarians! This program is actually based on [flask-script](#), so you may wonder why we use flask for something that is not web related at all; the point is that we use flask as an application framework more than a web framework.

`templates/` is... well, it contains templates. They are written with [jinja](#) templating language. The `render_template` function

documentation

Documentation is kept on `doc/source/` and is comprised of `.rst` files. The syntax used is [restructuredText](#). Don't forget to update documentation when you change something!

6.3.3 API

You can read [API](#)

6.3.4 Coding style

[PEP8](#) must be used in all the code.

Docstrings are used for autogenerating api documentation, so please don't forget to provide clear, detailed explanation of what the module/class/function does, how to use it, when is it useful, etc. If you want to be really nice, consider using [restructured-text directives](#) to improve the structure of the documentation: they're fun to use.

We care a lot about documentation, so please don't leave documentation out-of-date. If you change the parameters that a function is accepting, please document it. If you are making changes to the end user's experience, please fix the user manual.

Never put "binary" files in the source. With 'binary', we also mean "any files that could be obtained programmatically, instead of being included". This is, for example, the case of `.mo`.

6.4 Testing

Unit tests are important both as a way of avoiding regressions and as a way to document how something behaves. If your code is testable, you should test it. Yes, even if its behaviour might seem obvious. If the code you are writing is not easy to test, you should think of making it more easy to test. We use [nose suite](#) to manage tests, you can run all the tests and read coverage summary by typing:

```
python setup.py test
```

We usually follow these simple steps to add new tests:

- create a directory named `test` inside the package you want to test
- create a file in this folder `test/test_sometestgroupname.py`
- write [test functions](#) inside this file

We prefer not to have one big file, instead we usually group tests in different file with a representative name. You can see a full testing example in the [preset package](#).

Note: if you are testing a new package remember to add the new package name in `cover-package` directive under `[nosetests]` section in `/setup.cfg` file.

6.5 Contributing

Like libreant? You can help!

We have a [bugtracker](#), and you are welcome to pick tasks from there :) We use it also for discussions. Our most typical way of proposing patches is to open a pull request on github; if, for whatever reason, you are not comfortable with that, you can just contact us by email and send a patch, or give a link to your git repository.

7.1 libreantdb

class libreantdb.DB(*es*, *index_name*)

This class contains every query method and every operation on the index

The following elasticsearch body response example provides the typical structure of a single document.

```
{
  "_index" : "libreant",
  "_type" : "book",
  "_id" : "AU4RleAfD1zQdqx6OQ8Y",
  "_version" : 1,
  "found" : true,
  "_source": { "_language": "en",
    "_text_en": "marco belletti pdf file latex manual",
    "author": "marco belletti",
    "type": "pdf file",
    "title": "latex manual",
    "_attachments": [{ "sha1": "dc8dc34b3e0fec2377e5cf9ea7e4780d87ff18c5",
      "name": "LaTeX_Wikibook.pdf",
      "url": "fsdb:///dc8dc34b3e0fec2377e5cf9ea7e4780d87ff18c5",
      "notes": "A n example bookLatex wikibook",
      "mime": "application/pdf",
      "download_count": 7,
      "id": "17fd3d898a834e2689340cc8aacdebb4",
      "size": 23909451}]
  }
}
```

add_book (***book*)

Call it like this: db.add_book(doc_type='book', body={'title': 'foobar', '_language': 'it'})

autocomplete (*fieldname*, *start*)

delete_book (*id*)

file_is_attached (*url*)

return true if at least one book has file with the given url as attachment

get_all_books (*size=30*)

get_book_by_id (*id*)

get_books_by_actor (*authorname*)

get_books_by_title (*title*)

get_books_multilanguage (*query*)

get_books_querystring (*query*, ***kargs*)

get_books_simplequery (*query*)

get_last_inserted (*size=30*)

increment_download_count (*id*, *attachmentID*, *doc_type='book'*)

Increment the download counter of a specific file

iterate_all ()

mlt (*_id*)

High-level method to do “more like this”.

Its exact implementation can vary.

modify_book (*id*, *body*, *doc_type='book'*, *version=None*)

replace the entire book body

Instead of *update_book* this function will overwrite the book content with param *body*

If param *version* is given, it will be checked that the changes are applied upon that document version. If the document version provided is different from the one actually found, an *elasticsearch.ConflictError* will be raised

setup_db (*wait_for_ready=True*)

Create and configure index

If *wait_for_ready* is *True*, this function will block until status for *self.index_name* will be *yellow*

update_book (*id*, *body*, *doc_type='book'*)

Update a book

The “body” is merged with the current one. Yes, it is NOT overwritten.

In case of concurrency conflict this function could raise *elasticsearch.ConflictError*

user_search (*query*)

This acts like a “wrapper” that always point to the recommended function for user searching.

Indices and tables

- `genindex`
- `modindex`
- `search`

A

`add_book()` (libreantdb.DB method), 19

`autocomplete()` (libreantdb.DB method), 19

D

`DB` (class in libreantdb), 19

`delete_book()` (libreantdb.DB method), 19

F

`file_is_attached()` (libreantdb.DB method), 19

G

`get_all_books()` (libreantdb.DB method), 19

`get_book_by_id()` (libreantdb.DB method), 19

`get_books_by_actor()` (libreantdb.DB method), 19

`get_books_by_title()` (libreantdb.DB method), 19

`get_books_multilanguage()` (libreantdb.DB method), 20

`get_books_querystring()` (libreantdb.DB method), 20

`get_books_simplequery()` (libreantdb.DB method), 20

`get_last_inserted()` (libreantdb.DB method), 20

I

`increment_download_count()` (libreantdb.DB method), 20

`iterate_all()` (libreantdb.DB method), 20

M

`mlt()` (libreantdb.DB method), 20

`modify_book()` (libreantdb.DB method), 20

S

`setup_db()` (libreantdb.DB method), 20

U

`update_book()` (libreantdb.DB method), 20

`user_search()` (libreantdb.DB method), 20
